Orders of Growth & Linked Lists

Discussion 7: October 10, 2018

1 Orders of Growth

When we talk about the efficiency of a function, we are often interested in the following: as the size of the input grows, how does the runtime of the function change? And what do we mean by "runtime"?

• square(1) requires one primitive operation: * (multiplication). square(100) also requires one. No matter what input n we pass into square, it always takes one operation.

input	function call	return value	number of operations
1	square(1)	1 · 1	1
2	square(2)	$2 \cdot 2$	1
:	:	:	i :
100	square(100)	$100 \cdot 100$	1
:	:	:	<u>:</u>
n	square(n)	$n \cdot n$	1

• factorial(1) requires one multiplication, but factorial(100) requires 100 multiplications. As we increase the input size of n, the runtime (number of operations) increases linearly proportional to the input.

input	function call	return value	number of operations
1	factorial(1)	1 · 1	1
2	factorial(2)	$2 \cdot 1 \cdot 1$	2
:	:	:	i:
100	factorial(100)	$100 \cdot 99 \cdots 1 \cdot 1$	100
:	:	i :	i:
n	factorial(n)	$n \cdot (n-1) \cdots 1 \cdot 1$	n

For expressing complexity, we use what is called big Θ (Theta) notation. For example, if we say the running time of a function foo is in $\Theta(n^2)$, we mean that the running time of the process will grow proportionally with the square of the size of the input as it becomes very large.

- Ignore lower order terms: If a function requires $n^3 + 3n^2 + 5n + 10$ operations with a given input n, then the runtime of this function is in $\Theta(n^3)$. As n gets larger, the lower order terms (10, 5n, and $3n^2$) all become insignificant compared to n^3 .
- Ignore constants: If a function requires 5n operations with a given input n, then the runtime of this function is in $\Theta(n)$. We are only concerned with how the runtime grows asymptotically with the input, and since 5n is still asymptotically linear; the constant factor does not make a difference in runtime analysis.

Kinds of Growth

Here are some common orders of growth, ranked from no growth to fastest growth:

- \bullet $\Theta(1)$ constant time takes the same amount of time regardless of input size
- $\Theta(\log n)$ logarithmic time
- $\Theta(n)$ linear time
- $\Theta(n \log n)$ linearithmic time
- $\Theta(n^2)$, $\Theta(n^3)$, etc. polynomial time
- $\Theta(2^n)$, $\Theta(3^n)$, etc. exponential time (considered "intractable"; these are really, really horrible)

In addition, some programs will never terminate if they get stuck in an infinite loop.

Questions

What is the order of growth for the following functions?

```
1.1 def sum_of_factorial(n):
        if n == 0:
            return 1
        else:
            return factorial(n) + sum_of_factorial(n - 1)
1.2 def bonk(n):
        total = 0
        while n >= 2:
            total += n
            n = n / 2
        return total
1.3 def mod_7(n):
        if n % 7 == 0:
            return 0
        else:
            return 1 + mod_7(n - 1)
```

Linked Lists

There are many different implementations of sequences in Python. Today, we'll explore the linked list implementation.

A linked list is either an empty linked list, or a Link object containing a first value and the rest of the linked list.

To check if a linked list is an empty linked list, compare it agains the class attribute Link.empty:

```
if link is Link.empty:
    print('This linked list is empty!')
else:
    print('This linked list is not empty!')
Implementation
class Link:
    empty = ()
    def __init__(self, first, rest=empty):
        assert rest is Link.empty or isinstance(rest, Link)
        self.first = first
        self.rest = rest
    def __repr__(self):
        if self.rest:
            rest_str = ', ' + repr(self.rest)
        else:
            rest_str = ''
        return 'Link({0}{1})'.format(repr(self.first), rest_str)
    @property
    def second(self):
        return self.rest.first
    @second.setter
    def second(self, value):
        self.rest.first = value
    def __str__(self):
        string = '<'
        while self.rest is not Link.empty:
            string += str(self.first) + ' '
            self = self.rest
```

return string + str(self.first) + '>'

Questions

2.1 Write a function that takes in a Python list of linked lists and multiplies them element-wise. It should return a new linked list.

If not all of the Link objects are of equal length, return a linked list whose length is that of the shortest linked list given. You may assume the Link objects are shallow linked lists, and that lst_of_lnks contains at least one linked list.

```
def multiply_lnks(lst_of_lnks):
    """
    >>> a = Link(2, Link(3, Link(5)))
    >>> b = Link(6, Link(4, Link(2)))
    >>> c = Link(4, Link(1, Link(0, Link(2))))
    >>> p = multiply_lnks([a, b, c])
    >>> p.first
    48
    >>> p.rest.first
    12
    >>> p.rest.rest.rest
    ()
    """
```

2.2 Write a function that takes a sorted linked list of integers and mutates it so that all duplicates are removed.

```
def remove_duplicates(lnk):
    """
    >>> lnk = Link(1, Link(1, Link(1, Link(5)))))
    >>> remove_duplicates(lnk)
    >>> lnk
    Link(1, Link(5))
    """
```

3 Midterm Review

3.1 Write a function that takes a list and returns a new list that keeps only the evenindexed elements of lst and multiplies them by their corresponding index.

def	<pre>even_weighted(lst): """</pre>
	>>> x = [1, 2, 3, 4, 5, 6] >>> even_weighted(x)
	[0, 6, 20]
	return [

The **quicksort** sorting algorithm is an efficient and commonly used algorithm to order the elements of a list. We choose one element of the list to be the **pivot** element and partition the remaining elements into two lists: one of elements less than the pivot and one of elements greater than the pivot. We recursively sort the two lists, which gives us a sorted list of all the elements less than the pivot and all the elements greater than the pivot, which we can then combine with the pivot for a completely sorted list.

First, implement the quicksort_list function. Choose the first element of the list as the pivot. You may assume that all elements are distinct.

Note: in computer science, "sorting" refers to placing elements in order from least to greatest, not putting things in categories

def	<pre>quicksort_list(lst): """</pre>
	>>> quicksort_list([3, 1, 4]) [1, 3, 4]
	if:
	pivot = lst[0]
	less =
	greater =
	return

3.3 Write a function that takes in a list and returns the maximum product that can be formed using nonconsecutive elements of the list. The input list will contain only numbers greater than or equal to 1.

```
def max_product(lst):
    """Return the maximum product that can be formed using lst
    without using any consecutive numbers
    >>> max_product([10,3,1,9,2]) # 10 * 9
    90
    >>> max_product([5,10,5,10,5]) # 5 * 5 * 5
    125
    >>> max_product([])
    1
    """
```

3.4 Complete redundant_map, which takes a tree t and a function f, and applies f to each node (2^d) times, where d is the depth of the node. The root has a depth of 0. It should mutate the existing tree rather than creating a new tree.
